## INTRODUCTION

When one substance dissolves in another substance, a **solution** is formed. A **solution** is a homogeneous mixture in which the components are uniformly mixed. A solution consists of **solute** (the species that is dissolved) and **solvent** (the medium in which the solute has dissolved). The solvent is usually present in larger amount than the solute. When water is the solvent, the solution is called an **aqueous solution**.

When an ionic compound dissolves in water, it dissociates into its constituent ions. Such a compound is a strong electrolyte and conducts electricity well in dilute aqueous solutions. For example, when NaCl dissolves in water, it dissociates into separate Na<sup>+</sup> and Cl<sup>-</sup> ions.

This process occurs as polar water molecules orient themselves around the sodium and chloride ions and pull them free from the solid crystal. Once removed from the solid crystal, the ions remain separated and surrounded by water molecules. There are no solid NaCl particles present, although in the solution, occasional contact between the Na<sup>+</sup> and Cl<sup>-</sup> ions, called **ion pairing**, does occur.

The ability of a substance to dissolve is called its **solubility**. The solubility of a substance in water is typically defined as the mass of the substance that will dissolve in 100 mL of water. Solubility is temperature-dependent and usually increases for solid solutes dissolving in a liquid solvent.
